

Population Dynamics

Max Flöttmann and Jannis Uhlendorf

June 12, 2007

1 Discrete Population Models

- Introduction
- Example: Fibonacci Sequence
- Analysing Difference Equations

2 Continuous Population Models

- Predator-prey Models: Lotka-Volterra Systems
- Example: Lynx - Snowhoe Hare

3 Catastrophe Model for Fishing

- The Problem
- The Model
- Steady States
- Phaseplane

Discrete Population Models

- Differential equation models require overlap of generations
- Often no overlap between the generations (e.g. salomon, snowdrops, *Octopus Vulgaris*)
- Difference equation:
 - ▶ $N_{t+1} = f(N_t) = N_t F(N_t)$
- Discrete time steps
- Can in general be solved analytically

Small Example

- e.g. $N_{t+1} = rN_t$, $r > 0 \Rightarrow N_t = r^t N_0$
- Two populations
- Life span: 1 year
- Bees
 - ▶ 100 Bees produce 90 new ones each year $\Rightarrow r = 0.9$
- Wasps
 - ▶ 100 Wasps produce 101 new ones each year $\Rightarrow r = 1.01$

Fibonacci Sequence

- Rabbit population
 - ▶ Rabbits take one month to mature
 - ▶ Each productive pairs bears a new pair
 - ▶ Rabbits never die
- $R_{n+1} = R_n + R_{n-1}$
- Golden ratio: $\frac{N_t}{N_{t+1}} \approx \frac{\sqrt{5}-1}{2} \approx 0.618$
- Golden angle:
 $\frac{\sqrt{5}-1}{2} * 360 = 222.5 \Rightarrow \phi = 137.5$

Analysing difference equations

- Remember: $N_{t+1} = f(N_t)$
- Steady state if $N_{t+1} = N_t$
- Example: $f(N_t) = N_t \exp[r(1 - \frac{N_t}{K})]$ (Ricker function)
 - ▶ $K \rightarrow$ max. capacity
 - ▶ $r \rightarrow$ intrinsic growth rate

Graphical Solution: Cobwebbing

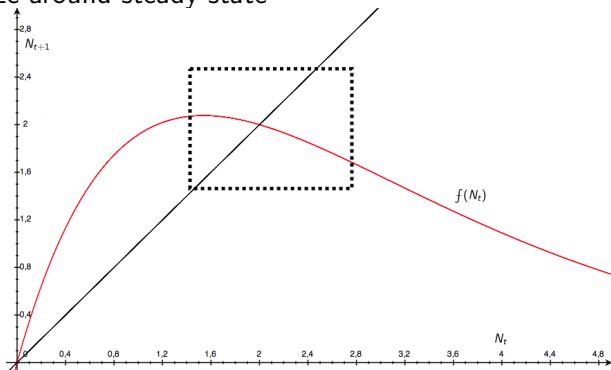

Steady State

- Steady state:
Intersections of the the curve $N_{t+1} = f(N_t)$ and the line $N_{t+1} = N_t$
- Stable steady state: small perturbation \Rightarrow system will fall back to steady state
- Derivative of $f(N_t)$ in the steady state determines stability

- Examine steady state in the example
- Linearize around steady state

Linearization Around Steady State

- Derivation: $\frac{df}{dN_t} \Big|_{N_t=N^*}$
- Linearization (1. Taylor expansion)

Stability: Graphical Solution

- This is a (linear) stable steady state

Stability: Graphical Solution

- slope > 1

- slope < -1

- $-1 < \text{slope} < 1$

- Observation:
Steady states with
abs. derivative < 1
are stable

Stability and Summary

- Stability: Small perturbations vanish
- Discrete case $x_{t+1} = Ax_t$:
 - ▶ Solution: $x_t = A^t x_0$
 - ▶ $\rho(\lambda)$ (max. abs. eigenvalue) $\leq 1 \Rightarrow$ Stability
- Continuous case $\frac{dx}{dt} = Ax$:
 - ▶ Solution: $x(t) = x_0 \cdot \exp(tA)$
 - ▶ $\nu(\lambda)$ (max. real part of eigenvalues) $\leq 0 \Rightarrow$ Stability
- Populations that reproduce in certain intervals \rightarrow difference equations
- Steady state: intersection of $N_{t+1} = f(N_t)$ and $N_{t+1} = N_t$
- Fibonacci sequence in plants

Continuous Population Models

- Most populations have overlap between generations (e.g Humans)
- Can to some extent be modeled by ODEs
- $\frac{dS}{dt} = f(S, t)$
- Good for large populations

Predator-Prey: Lotka-Volterra Systems

- Simple predator prey model
- $\frac{dN}{dt} = N(a - bP)$
- $\frac{dP}{dt} = P(cN - d)$
 - ▶ a growth rate prey
 - ▶ b neg. effect of predator on prey
 - ▶ c benefit of prey for predator
 - ▶ d decay rate of predator
- prey in absence of predator grows unbounded
- predator reduces prey's growth rate
- without prey the predator decays exponentially

Predator-Prey: Lotka-Volterra Systems

Timecourse

Phasediagram

Example: Lynx - Snowshoe Hare

- Lynx hunt snow hares
- Long term data available (1845 - 1930)
- Data from fur catch records
 - ▶ Assumption: Fixed proportion of the population was caught

Timecourse Lynx Hare

Phase Diagram 1910 - 1935

Time Course 1875 - 1904

Phase Diagram 1875 - 1904

Does the hare eat the lynx?

- Proposal: The hare carries a disease
 - ▶ No such disease known
- Hunting is the disease
- Data does not represent a fixed proportion

Summary

- Non overlapping generations \rightarrow discrete models
 - ▶ Stability: max. abs. eigenvalue ≤ 1
- Difference equations occur in nature
- Overlap and continuous behaviour \rightarrow ODE models
 - ▶ Stability: max. real part of eigenvalue ≤ 0
- Modeling populations can involve traps

1 Discrete Population Models

- Introduction
- Example: Fibonacci Sequence
- Analysing Difference Equations

2 Continuous Population Models

- Predator-prey Models: Lotka-Volterra Systems
- Example: Lynx - Snowhoe Hare

3 Catastrophe Model for Fishing

- The Problem
- The Model
- Steady States
- Phaseplane

Peruvian Anchovies

Figure: Fishing is a large economic sector in Peru

Peruvian Anchovies

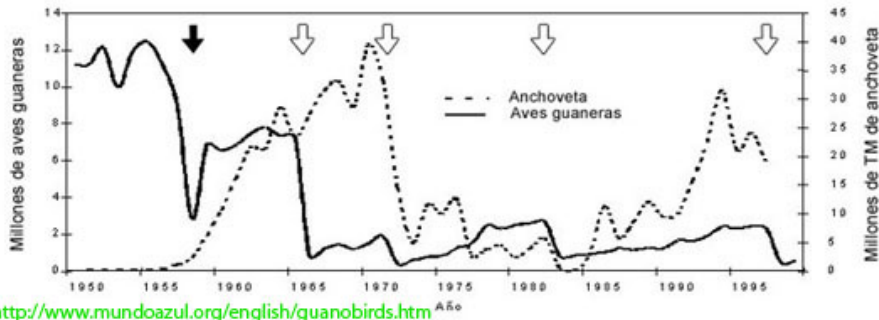

Figure: Sudden breakdown after many years of fishing.

Why?

Question: Why did this breakdown happen so sudden?

Why?

Approach: Mathematical modeling!

How to Model the Problem

What has to be taken into account?

How to Model the Problem

What has to be taken into account?

Biology

- population size
- growthrate of anchovies
- amount of harvested fish

How to Model the Problem

What has to be taken into account?

Biology

- population size
- growthrate of anchovies
- amount of harvested fish

Economy

- number of trawlers
- price for fish
- costs for fishing

Biology

How can the growthrate of anchovies be modelled?

How can the growthrate of anchovies be modelled?

- We could use a simple *logistic equation* like this:

$$x' = rx\left(1 - \frac{x}{K}\right) \quad (1)$$

Biology

- But:

Biology

- But:
 - ▶ Anchovies live in huge swarms

Biology

- But:
 - ▶ Anchovies live in huge swarms
 - ▶ The bigger the swarm the better the chances for survival and to find a partner

Biology

- But:
 - ▶ Anchovies live in huge swarms
 - ▶ The bigger the swarm the better the chances for survival and to find a partner
- So this function fits better:

$$x' = rx^2\left(1 - \frac{x}{K}\right) \quad (2)$$

- We add a small constant for fishes that can't be caught:

$$x' = a + rx^2\left(1 - \frac{x}{K}\right) \quad (3)$$

- We add a small constant for fishes that can't be caught:

$$x' = a + rx^2\left(1 - \frac{x}{K}\right) \quad (3)$$

- Finally we subtract the amount of fish that is harvested:

$$x' = a + rx^2\left(1 - \frac{x}{K}\right) - vEx \quad (4)$$

- We add a small constant for fishes that can't be caught:

$$x' = a + rx^2\left(1 - \frac{x}{K}\right) \quad (3)$$

- Finally we subtract the amount of fish that is harvested:

$$x' = a + rx^2\left(1 - \frac{x}{K}\right) - vEx \quad (4)$$

- But how is E defined?

Economy

- We build a strongly simplified model of Economy:

Economy

- We build a strongly simplified model of Economy:
 - ▶ an abstract value for fishing effort E

Economy

- We build a strongly simplified model of Economy:
 - ▶ an abstract value for fishing effort E
 - ▶ fish has a price p

Economy

- We build a strongly simplified model of Economy:
 - ▶ an abstract value for fishing effort E
 - ▶ fish has a price p
 - ▶ fishing has certain costs c

Economy

- We build a strongly simplified model of Economy:
 - ▶ an abstract value for fishing effort E
 - ▶ fish has a price p
 - ▶ fishing has certain costs c
 - ▶ v is the fishing yield per inset unit E

Economy

- We build a strongly simplified model of Economy:
 - ▶ an abstract value for fishing effort E
 - ▶ fish has a price p
 - ▶ fishing has certain costs c
 - ▶ v is the fishing yield per inset unit E
- This yields the equation:

$$E' = \alpha E(pvx - c) \quad (5)$$

The final Model

$$x' = a + rx^2\left(1 - \frac{x}{K}\right) - vEx \quad (6)$$

$$E' = \alpha E(pvx - c) \quad (7)$$

- a : small constant for remaining fishes
- r : linear growth factor
- K : unharvested equilibrium density
- v : gain per investement
- p : price for fishes
- c : cost per inset
- α : small factor to represent that E is a slow changing variable

Time Series

What is this Model good for?

- 1 We can analyse the behaviour of the model.
- 2 We can change parameters and get different results.
- 3 We can predict future developments and try to react before catastrophe happens.

Steady States

Figure: Stable steady state at high population

Steady States

Figure: bifurcation point

Steady States

Figure: three steady states

Steady States

Figure: stable steady state at low level

Phaseplane

Figure: The Phaseplane with coloring by gradient

Hysteresis

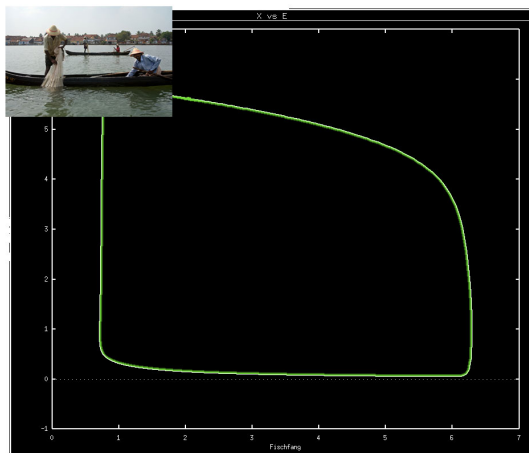

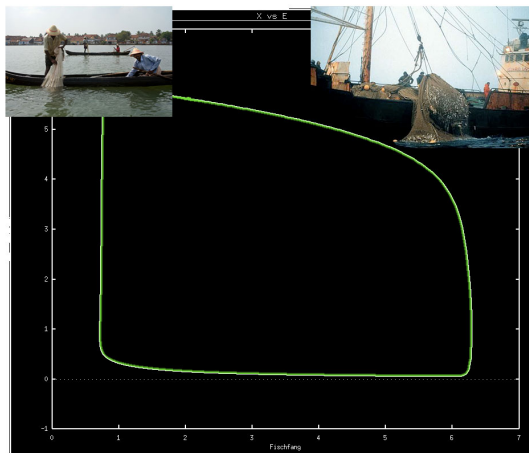

Figure: hysteresis - a memory of the system

Low Harvest

High Harvest

After Catastrophe

Regeneration

There are even worse cases!

Figure: new fishes have to be added to the environment

Maximum Sustainable Yield

- maximum value for fishing before the breakdown occurs
- can be predicted, but should be used carefully
 - ▶ many different prediction methods with different outcomes
 - ▶ parameters are hard to determine
 - ▶ at MSY minimal disturbances can lead to breakdown of population

WWF klagt gegen Kabeljau-Überfischung

Montag 19. März 2007, 12:12 Uhr

Hamburg (ddp-nrd). Die Umweltstiftung World Wide Fund für Nature (WWF) klagt seit Montag vor dem Europäischen Gerichtshof in Luxemburg gegen die Überfischung des Kabeljaus durch die Flotte der Europäischen Union. «Wir ziehen jetzt die juristische Notbremse gegen das andauernde Versagen der Fischereipolitik», sagte die Sprecherin der Organisation, Karoline Schacht, am Montag in Hamburg.

Nach Angaben des WWF ist die Zahl der geschlechtsreifen Dorsche in Nordsee, Irischer See, im östlichen Ärmelkanal und an der schottischen Westküste unter die Mindestmenge gefallen. Nach Artikel 7 des Kabeljau-Wiederaufbauplans müssten deshalb die Fangquoten um mehr als 15 Prozent gesenkt werden. Der EU-Fischereirat hat der Sprecherin zufolge jedoch nur eine Reduzierung der Fangquoten um 14 Prozent beschlossen. Die EU breche ihre eigenen Umweltgesetze, erklärte Schacht. Das dürfe nicht ungestraft geschehen.

«Den Zahlen nach geht es hier nur um wenige Prozentpunkte. Tatsächlich aber streiten wir für die Zukunft einer der ökologisch und wirtschaftlich wichtigsten Fischarten», betonte Schacht.
